---

version of the genome has been successfully reconstructed from a sample of human skin cells. The researchers, from the Wellcome Trust Sanger Institute and the University of Edinburgh, say the ability to recreate a whole genome allows scientists to study it in detail, look for effects of inherited diseases, and potentially develop a biological test for cancer. Traditionally, DNA has been studied by extracting a large amount of genetic material from a sample and then sequencing the DNA to create a sequence of the chemical building blocks of DNA (A, G, C, and T). The technique is lengthy and expensive, and only works on a small number of samples. The new method, published today in the journal *Nature*, uses cells grown from a small piece of a patient's own tissue. These samples, called cells in culture, are mixed together with DNA-slicing molecules that match the sequence on the genome, and then a cell-

---

decapitating enzyme is added to "cut up" the mixture. The rest of the genome is then purified and sequenced - this time using technology that can analyse millions of fragments at once. This technique works in a similar way to bioprinting, which has previously been shown to work for creating biological structures from a print head's nozzle. The results of the new technique will be published soon in a paper in the journal Nature Genetics. Part of the Human Genome Project
